## Pentatope Numbers

The third diagonal of Pascal's Triangle gives the number sequence

| 1 | 5 | 15 | 35 | 70 | 126 |
| :--- | :--- | :--- | :--- | :--- | :--- |

If we construct a forward difference table and extend back a remarkable pattern emerges.

| Start with | 1 | 5 | 15 | 35 | 70 | 126 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 4 | 10 | 20 | 35 | 56 |  |  |
|  |  | 6 | 10 | 15 | 21 |  |
|  |  |  | 4 | 5 | 6 |  |
|  |  |  |  | 1 | 1 |  |

Now extend back that 456 sequence to $0 \quad 1 \quad 2 \quad 3 \quad 4 \quad 5 \quad 6$

| 0 | 0 | 0 | 0 | 1 | 5 | 15 | 35 | 70 | 126 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 1 | 4 | 10 | 20 | 35 | 56 |  |
| 0 | 0 | 1 | 3 | 6 | 10 | 15 | 21 |  |  |
| 0 | 1 | 2 | 3 | 4 | 5 | 6 |  |  |  |

So we have a sequence of numbers that appears to be a quartic and gives as the first four terms the value 0 .

Taking the first term as $\mathrm{n}=0$ and using standard techniques the generating equation can be shown to be $\left(x^{4}-6 x^{3}+11 x^{2}-6 x\right) \div 24$. But consider that factorisation is possible. As the terms are 0 for the first four terms that suggests the factors must be $x,(x-1),(x-2)$ and $(x-3)$.

By examination, it can be seen that the term $\div 24$ must be retained and indeed the equation is $\left(x^{4}-6 x^{3}+11 x^{2}-6 x\right) \div 24=x(x-1)(x-2)(x-3) \div 24$.

Pentatope numbers are the number of intersections of lines connecting all vertices of an n-gon, with the additional proviso that you need to make the $n$-gon slightly irregular so that every two-line intersection is discreet. The number of possible vertices of an $n$-gon is easily shown to be $1 / 2 \mathrm{n}(\mathrm{n}-3)$

So the consequential number of intersections multiplies this by the additional term $(n-2)(n-3) / 12$. I have yet to deduce exactly why this is so, but it is probably connected with Euler's formula and a bit of combinatorics.
